1. As shown in Figure 1 multiple point charges are fixed in space, making an electric field \mathbf{E} . At the origin O the electric field is given by $\mathbf{E} = (-1.2, 3.2) \times 10^3 \text{ N/C}$.

Figure 1:

(a) Now, a charge $q = 6.5 \mu\text{C}$ is placed at $P = (2.0, 0)$ m anew. What is the electric field (vector!) at the origin now? [5]

Superposition

E by a single charge, magnitude = kQ/r^2

The electric field at the origin due to the charge q at P is, pushing outward from P and with magnitude $kq/r^2 = 9 \times 10^9 \times 6.5 \times 10^{-6} / 2^2 = 14.625 \times 10^{9-6} = 14.625 \times 10^3 \text{ N/C}$. Thus, $(-14.625, 0) \times 10^3 \text{ N/C}$ is the field at O due to q at P .

Now, the total field at O is $(-14.625, 0) \times 10^3 + (-1.2, 3.2) \times 10^3 = (-15.825, 3.2) \times 10^3 \text{ N/C}$.

Its magnitude is $\sqrt{15.825^2 + 3.2^2} \times 10^3 = 16.15 \times 10^3 \text{ N/C}$.

(b) Now, the charge q in (a) is moved from P to the origin. What is the force (vector) acting on q ? [5]

$F = qE$

There is no self interaction, so the field acting on the charge at the origin is the original $\mathbf{E} = (-1.2, 3.2) \times 10^3$.

Therefore, $F = 6.5 \times 10^{-6} \times (-1.2, 3.2) \times 10^3 = (-7.8, 20.8) \times 10^{-3} \text{ N}$

2. Electric field lines due to multiple charges (and other charges outside the figure window) on a plane are depicted in Fig. 2.

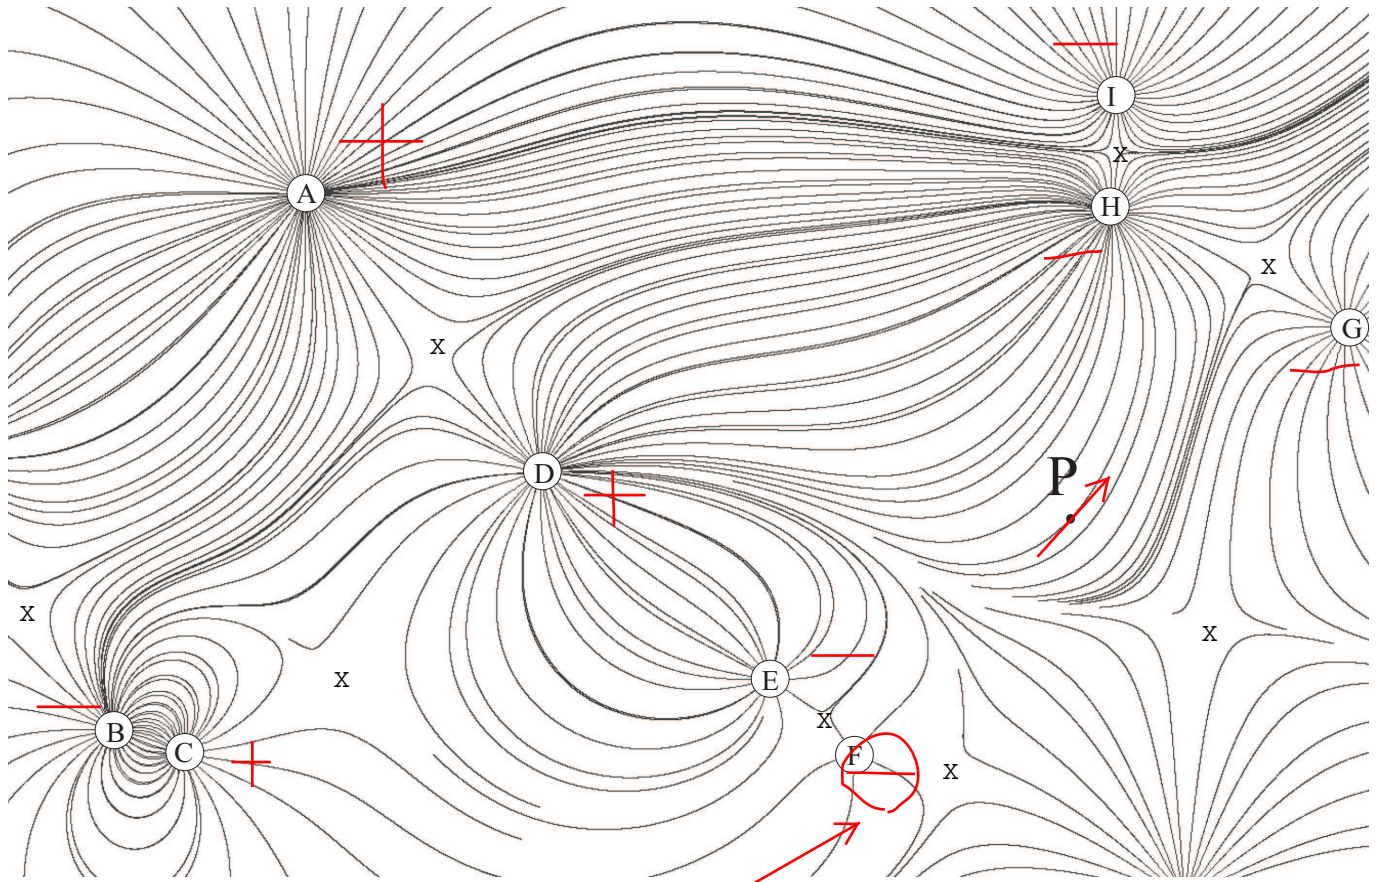

Figure 2:

(a) Suppose charge F is negative. Tell all the positive charges. [5]

A, C, D

(b) There are locations where the electric field is zero. Mark at least four (4) such locations with X. [3]

(c) Indicate the direction of the electric field at point P. You must briefly justify your choice. [2]

E is + to -, tangential to the force lines.
