1. Two straight thin wires A and B are perpendicular to the page as illustrated in the figure. Wire A carries a current of 3.6 A in the directions as indicated in the figure.

(1) The magnetic field at P happens to be zero. What is the current through wire B? Its magnitude and direction must be answered with justification. [5]

Ampere's law, RH screw rule  
 $B = \mu_0 I / (2\pi r)$

B due to B  
 RH screw rule tells us  
 current B must be into the page

Magnitude:  $B = \mu_0 I / (2\pi r)$

$r_A = 3 \text{ m}$ ,  $r_B = 2 \text{ m}$ .

Therefore,  $I_A/r_A = I_B/r_B$  is required.  $\rightarrow I_B = I_A(r_B/r_A) = 3.6(2/3) = 2.4 \text{ A}$ .

(2) Now the current through wire A is modified and the force acting on wire A is 3 mN per 1 m. What is the force acting on wire B per 1 m? (5)

$F = ILB \sin \phi$

But this is the problem of the action-reaction principle.

The same.

2. On the  $xy$  plane is a closed square loop of wire enclosing an area  $A = 4.1 \times 10^{-4} \text{ m}^2$ . The wire carries a permanent current of  $I = 121 \text{ A}$  as shown in the figure.

(1) A uniform magnetic field  $\mathbf{B}$  with magnitude  $1.3 \text{ T}$  makes a certain angle  $\theta$  with the positive  $z$ -axis as illustrated twists the loop with a torque of  $4 \times 10^{-2} \text{ N}\cdot\text{m}$ . What is the angle  $\theta$ ? [5]

$$\tau = NIAB \sin \phi$$

$$\begin{aligned} \sin \theta &= \tau / IBA \\ &= 4 \times 10^{-2} / 121 \times 1.3 \times 4.1 \times 10^{-4} \\ &= 4 \times 10^{-2} / 0.0645 = 0.62 \end{aligned}$$

Therefore,  $\theta = 38.3 \text{ deg}$ .

(2) After turning off the magnetic field, a bar magnet parallel to the  $x$ -axis is placed on the  $x$ -axis as illustrated below while the loop with the same current as in (1) is fixed. Then, the loop is gently released so that it can freely rotate around the origin. What happens to the loop shortly after it is released? [e.g., it starts to rotate around  $\dots$  as shown by the arrow (that you draw) in the figure.] [5]
